## Collaborative Learning

**Collaborative learning:** A task of learning a common objective among multiple computing agents without any central node and by using on-device computation and local communication among agents.

- In context of machine learning and optimization
- Applications in
  - Distributed deep learning
  - Industrial IoT
  - Smart Healthcare

We consider the *decentralized* implementation:

- general data-parallel setting
- the data is distributed across different computing nodes
- local computation
- communication among neighbors

## Challenges in Decentralized Implementation

### Straggling nodes

Nodes randomly slow down in their local computation.

### Communication load

Message passing algorithm induces large communication overhead.

### Our Goal

To develop decentralized optimization methods while addressing the above two challenges, i.e. *robust* and *communication-efficient*.

## Problem Setup

- Stochastic learning model

$$\min_{\mathbf{x}} \mathbb{E}_{\theta \sim \mathcal{P}} [\ell(\mathbf{x}, \theta)]$$

- Empirical risk model

$$\min_{\mathbf{x}} L_N(\mathbf{x}) := \min_{\mathbf{x}} \frac{1}{N} \sum_{k=1}^N \ell(\mathbf{x}, \theta_k)$$

- Collaborative learning model

- A network of  $n$  nodes, weight matrix  $W$

- Local loss for node  $i$

$$f_i(\mathbf{x}) := \frac{1}{m} \sum_{j=1}^m \ell(\mathbf{x}, \theta_i^j)$$

- Global loss

$$\min_{\mathbf{x}} f(\mathbf{x}) := \frac{1}{n} \sum_{i=1}^n f_i(\mathbf{x}) = \min_{\mathbf{x}} \frac{1}{mn} \sum_{i=1}^n \sum_{j=1}^m \ell(\mathbf{x}, \theta_i^j)$$

## Our Proposal: QuanTimed-DSGD

At iteration  $t$  and node  $i$ :

- *Deadline-Based Gradient Computation*

- A deadline  $T_d$  is fixed
- Node  $i$  computes gradients on (random) sample subset  $\mathcal{S}_{i,t}$

$$\tilde{\nabla} f_i(\mathbf{x}_{i,t}) = \frac{1}{|\mathcal{S}_{i,t}|} \sum_{\theta \in \mathcal{S}_{i,t}} \nabla \ell(\mathbf{x}_{i,t}; \theta)$$

- Computation time: random speed  $V_{i,t} \sim F_V \Rightarrow |\mathcal{S}_{i,t}| = T_d V_{i,t}$

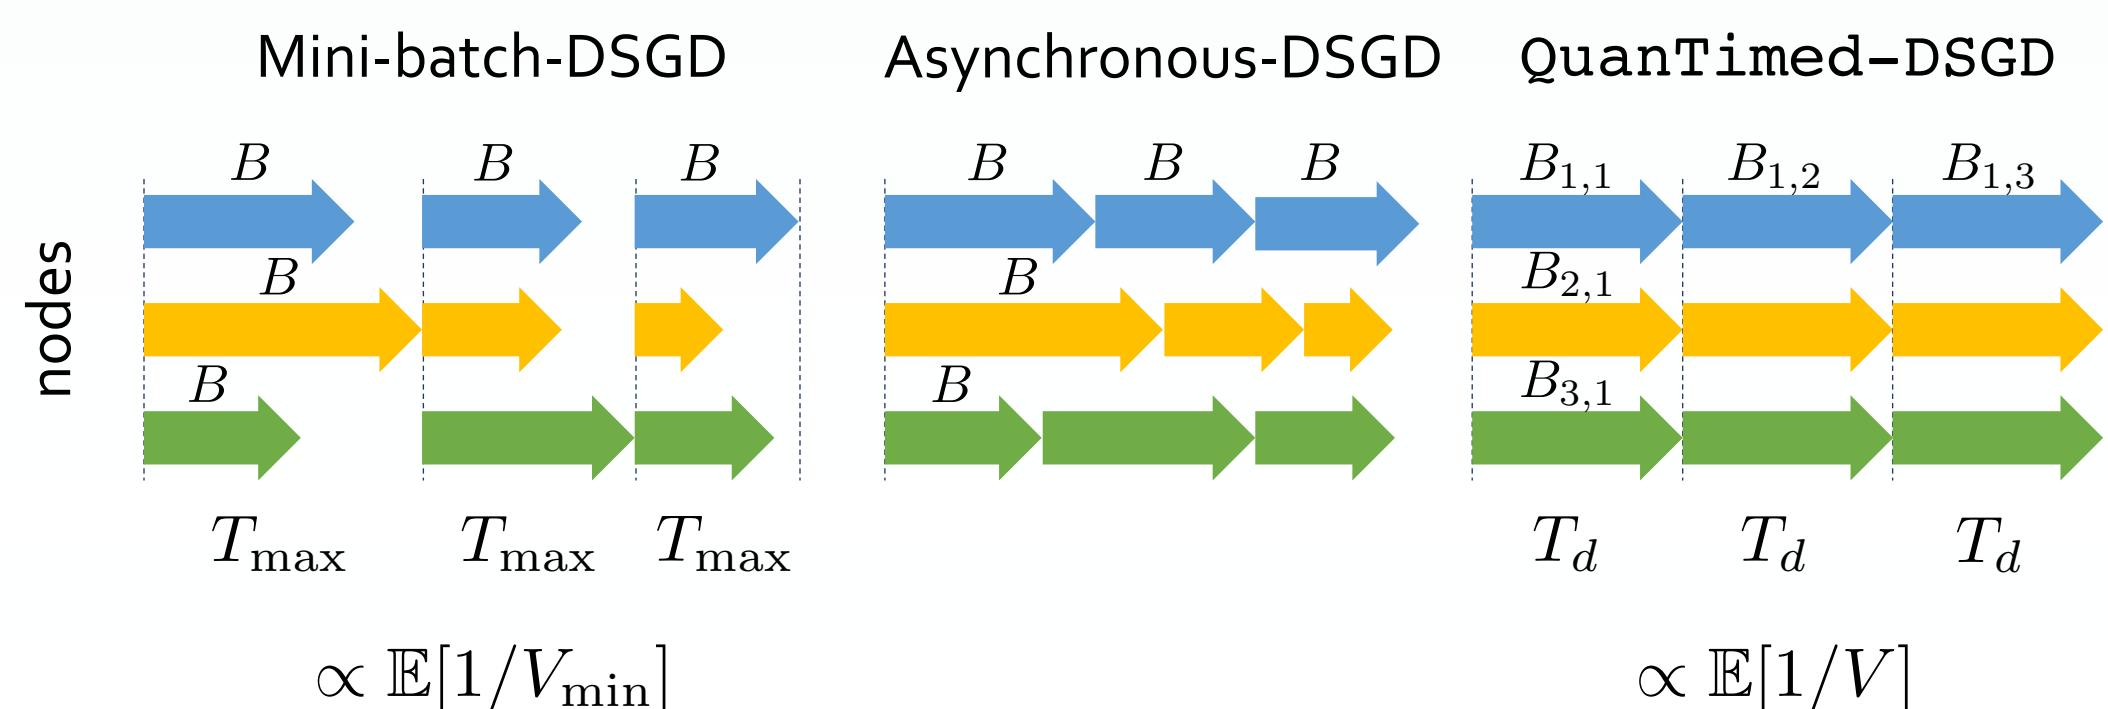

- *Quantized Message-Passing*

- Nodes exchange quantized models  $\mathbf{z}_{i,t} = Q(\mathbf{x}_{i,t})$

- *Update*

$$\mathbf{x}_{i,t+1} = (1 - \varepsilon + \varepsilon w_{ii}) \mathbf{x}_{i,t} + \varepsilon \sum_{j \in \mathcal{N}_i} w_{ij} \mathbf{z}_{j,t} - \alpha \varepsilon \tilde{\nabla} f_i(\mathbf{x}_{i,t})$$

- ✓ Iteration time implication:

## QuanTimed-DSGD in Theory

### Assumptions.

- A1. Weight matrix  $W$  is doubly stochastic.
- A2. Random quantizer  $Q(\cdot)$  is unbiased & variance-bounded.
- A3. Loss function  $\ell$  is  $K$ -smooth.
- A4. Stochastic gradients  $\nabla \ell(\mathbf{x}; \theta)$  are unbiased & variance-bounded.

### Convergence for non-convex losses

- ✓ Assumptions A1-4
- ✓ Large enough iterations  $T$
- ✓ Pick step-sizes  $\alpha = T^{-1/6}$  and  $\varepsilon = T^{-1/3}$

$$\frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E} \|\nabla f(\bar{\mathbf{x}}_t)\|^2 = \mathcal{O}\left(\frac{1}{T^{1/3}}\right)$$

$$\frac{1}{T} \sum_{t=0}^{T-1} \frac{1}{n} \sum_{i=1}^n \mathbb{E} \|\bar{\mathbf{x}}_t - \mathbf{x}_{i,t}\|^2 = \mathcal{O}\left(\frac{1}{T^{1/3}}\right)$$

- A5. Loss function  $\ell$  is  $\mu$ -strongly convex.

### Convergence for strongly-convex losses

- ✓ Assumptions A1-5
- ✓ Pick  $\delta \in (0, 1/2)$
- ✓ Large enough iterations  $T$
- ✓ Pick step-sizes  $\alpha = T^{-\delta/2}$  and  $\varepsilon = T^{-3\delta/2}$

$$\frac{1}{n} \sum_{i=1}^n \mathbb{E} \|\mathbf{x}_{i,t} - \mathbf{x}^*\|^2 = \mathcal{O}\left(\frac{1}{T^\delta}\right)$$
